    <title>Hello Javascript!</title>

    <!--
      This document has simple code to explore basic javascript

      Created: 4. Feb 2015
      5. Feb 2015 -simplified document to for a less complicated intro
                  -notice that html comments use a certain kind of tag?
    -->

    <!-- almost all of your javascript code will be in the <head> of your HTML file -->
    <script>

      /*
        This function changes the button text wittily after being clicked.
        Oh! The comedy!

        It looks for the HTML element that has an id of "helloButton" and replaces
        anything inside that element with "Hello World!"

        Notice that the 'grammar' changes in the <script> area. You are now in
        javascript territory. Comments should be tagged with the slashes and asterices.

        (You can get away with HTML comment tags in here, but that habit will mess
        you up if you do that in external javascript files. So don't.)

      */

      function buttonChanger () {
        document.getElementById("helloButton").innerHTML ="Hello World!";
      }

    </script>
  </head>

  <body>
    <h2>Hello Javascript</h2>

    <!--
      Make a button that triggers a function when clicked

      It is good form to make the name= and id= of a form element to be the same.
      The name= is not important for most Javascript programming, but it would make
      a difference if you were submitting the form to a server for processing.
    -->

    <button type="button" id="helloButton" name="helloButton" onclick="buttonChanger();">
      Wait! Don't click me!
    </button>
  </body>
</html>
```
